Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

Description

This invention pertains to a new lithium-containing binder composition suitable for use in bonding a particulate material such as alumina, magnesia, or other aggregate material to make a shaped refractory article.

It is known in the art to employ phenol-formaldehyde resole resins to bond granular refractory material for use in, for example, a foundry molding composition or a refractory article. For example, U.S. Patent 4,426,467 to Quist, et al. discloses such a composition which is curable at room temperature in the presence of an alkali such as sodium or potassium, using a lactone as curing agent. The composition contributes to the dimensional stability of articles produced therefrom via refractory bonding (i.e., through durable carbon-carbon bonds and carbon-aggregate bonds) and also provides abrasion resistance.

It is also known to use a phenol-formaldehyde novolac resin to bond a carbonaceous aggregate as is disclosed in Chandramouli, et al., U.S. 4,775,455, issued October 4, 1988; (assigned to the assignee of the present invention).

Ester curable phenol formaldehyde resole resins are alkaline in nature, i.e., containing potassium or sodium alkali or mixtures thereof. Such resins are disclosed in U.S. Patent 4,474,904 to Lemon, et al. Use of lithium or magnesium salts of lower alkanolic and inorganic acids is known for imparting hot green sand workability in foundry mold applications (see U.S. Patent 4,131,476 to Melcher et al.). Use of lithium ions as the alkalizing agent to facilitate ester cure of resole resins for use in refractory articles is heretofore not demonstrated.

SUMMARY OF THE INVENTION:

Accordingly, the present invention provides a lithium ion-containing binder for refractory articles, which binder cures at room temperature in the presence of an ester functional curing agent. The lithium ion-containing binders of the present invention are also useful for preparing coatings and toppings for various substrates, including but not limited to, concrete. In the absence of an ester-functional curing agent, the binder cures when exposed to elevated temperatures. Refractory articles produced from the binder and an aggregate exhibit higher tensile strengths and higher compressive strengths relative to sodium ion-containing or potassium ion-containing binder systems, after exposure to elevated temperatures.

In one aspect of the invention, a raw batch composition for use in making a shaped article, e.g., a refractory article, is provided. The composition comprises a mixture of (a) an aggregate material; (b) a curable resole resin binder solution wherein the resole is present in sufficient quantity to bond the aggregate into a desired shape; (c) an ester-functional curing agent in an amount sufficient to effect curing of the binder; and (d) a lithium ion-generating alkalizing agent, such as lithium hydroxide, wherein the resole resin has a formaldehyde:phenol ratio in the range of about 1:1 to about 3:1, and wherein the weight ratio of the resole resin to aggregate is from about 2:100 to about 1:7, and wherein the ester-functional curing agent is selected from the group consisting of lactones, cyclic organic carbonates, carboxylic acid esters, and mixtures thereof. The curing agent may be present in the composition at a level of about 3% to 40% based on the weight of the resole resin.

By "phenol formaldehyde resole" herein is meant resole resins, polymers, copolymers, terpolymers or mixtures comprising a phenolic material such as phenol cresol, or xylenol or mixtures thereof, and formaldehyde.

In another aspect, a shaped article is provided, the shaped article comprising an aggregate material bonded together by a resin binder, the binder comprising a cured phenol formaldehyde resole resin, wherein the resin prior to curing comprises (i) a phenol formaldehyde resole resin having a formaldehyde:phenol mole ratio in the range of about 1:1 to about 3:1, and wherein the resin binder is cured in the presence of sufficient lithium ions to induce cure using a curing agent selected from the group consisting of lactones, cyclic organic carbonates, carboxylic acid esters, aromatic formates and acetates and mixtures thereof.

In a further aspect, the invention relates to a process for making a refractory body that can be sintered to form a carbonized article. The body is prepared from an aggregate material; a resin binder comprising a phenol formaldehyde resole resin or a phenol formaldehyde novolac resin and a phenol formaldehyde resole resin, as specified above; a lithium ion-generating alkalizing agent; and an ester-functional curing agent in an amount sufficient to effect ambient temperature curing of the resin binder. The process comprises the steps of (a) mixing aggregate with resin binder and adding an ester-functional curing agent to coat the aggregate until a binder-aggregate mixture is formed; (b) forming the binder-aggregate mixture into a desired shaped article; (c) optionally allowing the article to stand to develop room temperature strength;

and (d) heating the shape to cure and carbonize the resin binder and thereby make a refractory body. It is envisioned that the exact amounts of components used can be varied outside the ranges indicated above, and the ranges are not provided as limitations.

Articles produced using the lithium-ion containing inventive binders display tensile and compression strengths significantly superior to articles produced using potassium ions or sodium ions as the alkali in the binders.

DESCRIPTION OF THE PREFERRED EMBODIMENTS:

It has been found that by using a lithium ion-generating material as the alkalizing agent necessary to promote ester cures of resole resins, improved properties of the resulting cured materials are achieved. The alkalizing agent of the present invention is one capable of providing to the binder composition a lithium ion. Preferred alkalizing agents include lithium oxide, lithium hydroxide, and mixtures thereof. Other sources of lithium ions are also effective in the present invention for catalyzing the cure of the resole resin, such as lithium alkoxides. These can include, for example, the lithium salt of an alcohol containing one to two carbons, such as lithium methoxide, lithium ethoxide, or monolithium salt of ethylene glycol. Materials, mixtures, or compounds containing among other components lithium oxide or lithium hydroxide are also operative herein, as long as the lithium ion level provides to the binder composition sufficient alkalinity to initiate the ester cure of the resole resin at room temperature. The mole ratio of lithium ion to phenol on the resin is for example, from about 0.1:1 to about 0.7:1. A preferred mole ratio is from about 0.3:1 to about 0.6:1.

The Raw Batch Composition

This invention is, in one aspect, a raw batch composition comprising an aggregate material, a resin binder, a lithium ion-generating alkalizing agent, and an ester-functional curing agent. The choices of the aggregate material, and of certain characteristics of the resin binder, are made according to the end product that is desired.

The aggregate material may be any material which may be bound with a resin binder to form a shaped refractory article such as a refractory brick for furnace lining. The aggregate material may be in granular, powder, flake or fibrous form. Suitable aggregate materials for use in refractory applications include, but are not limited to, magnesia, alumina, zirconia, silica, silicon carbide, silicon nitride, boron nitride, bauxite, quartz, corundum, zircon sand, olivine sand, and mixtures thereof. For certain applications, low density aggregate materials such as vermiculite, perlite and pumice are preferred. For other applications, preferable high density aggregates include limestone, quartz, sand, gravel, crushed rock, broken brick and air-cooled blast furnace slag.

One of the constituents of the resin binder of the present invention is a phenol formaldehyde resole resin. A resole resin is the generally alkaline resinous reaction product of a phenolic material and an aldehyde. The phenolic material used herein can be, for example, phenol, cresol, xyleneol and mixtures thereof. The resole resin has sufficient residual methylol reactivity such that it may be cured by heat to a water-insoluble and thermally infusible condition, without the addition of a curing agent.

The resole resin useful in the present invention is one having a formaldehyde:phenolic material mole ratio in the range of about 1:1 to about 3:1, and preferably about 1.6:1 to about 2.4:1. The resole resin is generally prepared by reacting the desired proportions of monomers at a pH of greater than about 7.5, and more preferably about 9 to 12. Resole resins useful herein may contain residual K^+ or Na^+ used in the preparation of the resole.

The weight average molecular weight of the resole can vary over a broad range such as from about 500 to about 2,000, and preferably in the range of about 700 to about 1,500.

The lithium ion-catalyzed resin binder composition of the present invention will customarily, but not necessarily, be an aqueous solution having a solids content of from about 40% to about 75% by weight. It is preferable to have a composition with a high solids content but if the viscosity is too high, the material becomes difficult to handle and mixing characteristics and performance decline. If the solids level of resin binder in the composition is too low, the viscosity is low and performance suffers due to insufficient binder level.

The lithium ion-generating alkalizing agent in the resin binder composition is present in any amount sufficient to produce a cure of the resole resin when the ester has been added. A preferred level of lithium ion-generating alkalizing agent is an amount sufficient to provide a molar ratio of lithium:phenol moiety on the resole resin in the range of about 0.1:1 to about 0.7:1, although all levels up to a lithium:phenol ratio of

about 1:1 are effective.

The ester-functional curing agent used in this invention is one known in the art as having at least one ester-functional group which is capable of catalyzing the cure of the resole resin at ambient conditions.

The ester-functional curing agent may be selected from the group consisting of lactones, cyclic organic carbonates, carboxylic acid esters, aromatic formates, and aromatic acetates, and mixtures thereof. Generally, it is preferred to use a curing agent having from 3 to 12 carbon atoms and more preferably from 4 to 9 carbon atoms. Gaseous esters, such as C₁-C₃ alkyl formates, are also acceptable curing agents in low density articles or when applying the binders to fabric or paper substrates. When gaseous esters are used as curing agents, the ester is generally not mixed with the resin binder and aggregate but rather is supplied as a gas to the shaped article as taught in U.S. Patent 4,468,359.

Examples of lactones which accelerate the room temperature cure or hardening of the resole resin binders of the present invention include, gamma-butyrolactone, valerolactone, caprolactone, beta-propiolactone, beta-butyrolactone, beta-isobutyrolactone, beta-isopentylactone, gamma-isopentylactone, delta-pentylactone, and epsilon-caprolactone.

Examples of organic carbonates which accelerate the room temperature cure of the resole resin binder of the present invention include, 1,2-propylene carbonate, 1,3-propylene carbonate, ethylene carbonate, glycerol carbonate, 1,2-butylene carbonate, 1,3-butylene carbonate, 1,2-pentylene carbonate and 1,3-pentylene carbonate.

Carboxylic acid esters which accelerate the cure of the resole resin binder include, methyl acetate, ethylene glycol diacetate, glycerol diacetate (diacetin), and glycerol triacetate (triacetin). In the case where a carboxylic acid ester is used, triacetin is preferred.

Other aliphatic monoesters may be suitable, such as formates, propionates, and butyrates. Additional aliphatic multiesters which may be suitable include diformate, diacetate, or higher diesters of ethylene glycol, diethylene glycol, 1,2-propylene glycol, glycerol, 1,3-propanediol, 1,2-butanediol, 1,3-butanediol, and 1,4-butanediol. Furthermore, diesters of dicarboxylic acids, such as dimethyl malonate, dimethyl glutarate, dimethyl adipate, and dimethyl succinate, are suitable.

Lower alkyl formates, gamma-butyrolactone, and propylene carbonate may be used, when rapid mixing, shaping, and curing is desired. Other esters of short and medium chain (e.g., one carbon to six carbons) alkyl monohydric or polyhydric alcohols, and short or medium chain carboxylic acids (e.g., carboxylic acids having one to six carbon atoms) may be used.

Also suitable as ester-functional curing agents in the present invention are aromatic esters such as the formates, acetates, and diacetates of the following: phenol, *o*-cresol, *m*-cresol, *p*-cresol and their mixtures, all isomers of xylene, *m*-ethyl phenol, resorcinol, catechol, hydroquinone, pyrogallol, phloroglucinol, chlorophenol, *o*-hydroxy diphenyl, *p*-hydroxy diphenyl, diphenylol methane, diphenylol propane, as taught in U.K. Patent Application GB 2140017A.

The ester-functional curing agent preferably is present in an amount sufficient to effect curing of the resole resin binder, typically at about 3% to about 30% by weight, based on the weight of phenolic resin and preferably about 5% to about 25%. A more preferred level of curing agent is 10% to 20%, based on the weight of the resin binder. For use in refractory articles according to the present invention, levels of ester-functional curing agent lower than the levels used for producing foundry articles are preferred, so as to leave unreacted at room temperature a percentage of the methylol sites and to decrease excess ester and its byproducts. These reactive methylol sites are then able to undergo thermal cure upon subsequent exposure of the article to heat. Therefore, it is preferable in the present invention to utilize levels of ester only so high as needed to cure the resole to an acceptable green strength without heat treatment.

It has also been found that, by employing a blend of a novolac component and a resole component, a resin binder may be formulated which is capable of lithium ion-catalyzed room temperature ester cure (chemical cure), followed by subsequent heat treatment (thermal cure). Such resin binders also have the desirable properties of low thermal conductivity and high dimensional stability and abrasion resistance. The ability of articles made from such lithium ion-catalyzed resin binders to withstand extremely high temperatures makes for a binder which is useful for refractory applications.

The lithium ion-catalyzed resin binders of the present invention can utilize a blend of novolac and resole components. By "component" herein is meant an individual resin or a blend, mixture, reaction product, or other combination of resins containing the novolac or resole of reference. A novolac resin is one prepared with a deficiency in aldehyde so that when used alone, it may not be cured unless a curing agent such as hexamethylene-tetramine ("hexa") is added. A novolac resin may be defined as the generally acidic resinous reaction product of a phenolic material and an aldehyde that, for practical purposes, does not harden or convert to an insoluble, infusible condition upon heating but remains soluble and fusible. By "novolac" herein is meant novolac resins, polymers, copolymers, terpolymers or mixtures comprising a

phenolic material such as phenol, cresol, or xyleneol or mixtures thereof, and formaldehyde. Novolac resins are not capable of ambient temperature ester cure (chemical cure). The formaldehyde:phenolic mole ratio of the novolac useful in the present invention is in the range of about 0.5:1 to about 0.9:1, and preferably about 0.6:1 to about 0.8:1, wherein the phenolic material is selected from phenol, o-, m-, and p-cresol, xyleneols and mixtures thereof. Preferably, the novolac resin is prepared by condensing formaldehyde and phenol at a pH of less than about 4, and more preferably about 2.

The resin binder may be prepared simply by dissolving or dispersing the resole, or by mixing the prescribed proportions of novolac component and resole component, in alkaline solvent solution. The preferred solvent is water but C₁-C₇ aliphatic and aromatic alcohols, C₂-C₄ glycols, glycol ethers, and (water-alcohol mixes also are acceptable.

In one embodiment of the present invention, the lithium ion-catalyzed resin binder, prior to cure, is preferably a 0.35:1 to 5:1 by weight mixture of (1) a phenol formaldehyde novolac component having a formaldehyde:phenol mole ratio in the range of about 0.5:1 to about 0.9:1, and (2) a phenol formaldehyde resole component having a formaldehyde:phenol mole ratio in the range of about 1:1 to about 3:1. The weight ratio of novolac to resole in the resin binder is more preferably in the range of about 0.5:1 to about 3:1.

The novolac component used in the alkaline solution may be in the form of, for example, a solution or powder.

Hexa and/or other methylene-generators, such as for example formaldehyde or paraformaldehyde, can be added to the resin binders of the present invention. When used, hexa is added at a level of about 3% to about 15%, based on the weight of total phenolic material, and more preferably at about 5% to about 10%.

The ester-functional curing agent cures the lithium ion-catalyzed resin binders (chemical cure) of the present invention at ambient conditions to thereby provide excellent green strengths. The inventive binders can be further cured or hardened by heat (thermal cure). The heat, if applied, can be heat from an oven or furnace or heat from, for example, molten material poured onto an article prepared from the resin binder and an aggregate. The heat also produces carbonization of the resin binder. Therefore, by "cure" herein is meant both the ester-functional room temperature curing agent acceleration of the cure or hardening of the resin binder, and also the subsequent heat and/or hexa-accelerated cure or hardening of the resin binder.

The aggregate material to be bound by the binder composition may be selected from magnesia, alumina, zirconia, silica, silicon carbide, silicon nitride, zircon sand, olivine sand, boron nitride, bauxite, chromite, corundum, pumice, perlite, vermiculite, limestone, quartz, sand, gravel, crushed rock, broken brick, air cooled blast furnace slag, and mixtures thereof. A particularly preferred aggregate for refractory uses is magnesia (magnesium oxide), which provides particularly good room temperature and post-heating strengths to articles prepared therewith.

The binder composition is generally added to the aggregate material at a weight ratio of resin to aggregate material of from about 3:100 to about 1:7 but preferably is present at about 3 to 10 weight percent.

The lithium ion-generating alkalizing agent can be dissolved or dispersed in the resole resin or a novolac resin, if present. The lithium ion-generating alkalizing agent is generally not soluble in the ester-functional curing agent.

The raw batch composition produced by combining the resin binder, aggregate, curing agent, and lithium ion may additionally comprise any of a number of optional modifiers or additives including non-reactive solvents, silanes, hexa, clays, graphite, iron oxide, carbon pitch, silicon dioxide, metal powders such as aluminum, magnesium, silicon, and calcium and magnesium hydroxides and oxides, and mixtures thereof. In foundry applications and sand-binder overlays, or where silica sand is used as the aggregate, a preferred additive is a silane adhesion promoter, such as gamma-aminopropyl triethoxysilane, which is used in amounts of, for example, up to 0.05% to 0.5% by weight, based on the total resin binder. In refractory applications, clays, metal powders (e.g. aluminum, magnesium or silicon), and graphite are preferred additives. When graphite or metal powders of aluminum, magnesium or silicon or mixtures thereof are used as additives, the amount of aggregate, such as alumina or magnesia, can be reduced to as low as about 70% by weight of the composition. Thus the composition can comprise 70-97% aggregate, 3-25% resin binder, and 0-27% graphite or metal powder additive.

The Shaped Refractory Article

The invention is, in a further aspect, a shaped refractory article comprising an aggregate material bonded together with the aforescribed lithium ion-catalyzed resin binder.

The aforescribed lithium ion-catalyzed binder compositions are mixed with the aggregate material and the ester-functional curing agent. Mixing may be accomplished in any means known in the art, i.e., using any industrial mixer such as an Eirich mixer, a Simpson mixer, a Muller mixer, and the like. The binder-aggregate mixture which results from the previous step may be molded by any technique known in the art and subjected to pressure to form a desired shape. For example, the binder-aggregate may be subjected to compression, isostatic pressing, transfer molding, extrusion or injection molding at desired temperatures and pressures.

Following shaping, a low density shape may be subjected to gassing with a gaseous or vaporous ester-functional curing agent and/or a series of heat treatment techniques as known in the art. When gassing the shape with an ester-functional curing agent, it is often not necessary to add a liquid ester-functional curing agent into the binder composition. A typical heat treatment involves a continual increase in temperature up to about 120°C (248°F) to 205°C (400°F) to effect thermal cure of the resin binder and evaporate off water and organic solvent. Further heat treatment up to 800°C to 1000°C further promotes carbonization of the resin binder.

Accordingly, shaped refractory articles which may be prepared include, for example, kiln furniture, hot tops, tundish liners, insulation, ceramic materials, and the like.

In yet other aspects, the invention relates to a process for preparing a shaped refractory article. In one aspect, the invention relates to a process for making a refractory body that can be pyrolyzed or sintered.

In a preferred embodiment of the process of the present invention, the temperature to which the shaped article is heated is in the range of 100°C to 150°C (212°F to 302°F).

In another preferred embodiment of the process of the present invention, the formaldehyde:phenol mole ratio of the resole resin is from about 2:1 to about 3:1, the ester-functional curing agent is triacetin, present at 17% or less based on the weight of the resole resin, the lithium ion-generating alkalizing agent is lithium hydroxide, present in an amount sufficient to produce a lithium:phenol molar ratio of about 0.2:1 to 0.7:1.

The preferred aggregate materials are alumina or magnesia, present at levels of from 70% to 97% by weight of the binder-aggregate mixture, depending on whether graphite or metal powder additives are also included.

Overlay Coating

The invention is, in another aspect, an overlay coating or topping applied to a rigid surface such as concrete. Thus a room temperature curable flooring composition is provided comprising a resin binder and aggregate system prepared as described above. Aggregates for the overlay coating can be selected from low or high density materials or mixtures thereof. The use of a lithium ion-generating alkalizing agent is preferred to sodium ion-generating or potassium ion-generating alkalizing agents in concrete applications because sodium and potassium ions more readily hydrate to form the hydroxides which are deleterious to the concrete aggregate. The trace amounts of sodium or potassium ions present in the instant compositions from the preparation of the resole resin are not sufficient to produce adverse effects on concrete.

The invention is illustrated by the following Examples which are intended merely for the purpose of illustration. Unless specifically indicated otherwise, parts and percentages are given by weight.

Example 1 Lithium Ion-Containing Resole.

A reactor was charged with phenol (940 grams, 10.0 moles) and 45% potassium hydroxide (62.2 grams, 0.50 mole). To this solution at 60°C was added over 30 minutes warm 50% aqueous formaldehyde (1074 grams, 17.9 moles) while the reaction temperature rose to 105°C. The reaction mixture was then cooled and held at 75 - 85°C until a Gardner viscosity (25°C) of T-U (approximately 5.9×10^{-4} m²/s (590 centistokes)) was reached. The solution was then rapidly cooled to room temperature. 644 grams of the solution (60.4% solids) was diluted with 88 grams water and 69 grams lithium hydroxide monohydrate was added with mixing. The lithium:phenol and potassium:phenol mole ratios in the resulting resole resin were 0.57:1 and 0.05:1, respectively.

To a 3.8 dm³ (1 gallon) Hobart mixer, charged with about 1.25 Kg of magnesia at 25 to 26°C (75 to 77°F) was added a 50% aqueous solution of the above lithium ion-catalyzed resole resin to produce a mixture containing 3% phenolic resin solids based on the weight of the magnesia aggregate. The magnesia was of -14 to +48 mesh size. The binder-aggregate mixture was mixed for 2 minutes followed by the addition to the mixture of 17% triacetin curing agent, based on the weight of the alkaline resole solution (i.e., about 8.5% triacetin based on resole resin solids). Mixing was continued for one minute. A 150 gram sample of the mix was charged to a dogbone die which was then subjected to a ramming pressure of

15241 Kg (15 tons) for 1 minute to produce a tensile strength test specimen. The specimens, 7.62 cm (3 inches) long, 2.22 cm (7/8 inch) thick and 2.54 cm (1 inch) wide at the neck, were allowed to stand 24 hours at 25°C and 42% to 48% relative humidity prior to being subjected to breaking on a Tinius Olsen tensile test machine. Some dogbone specimens after the 24 hours at 25°C were subjected to a 40 hour temperature cycling, which includes 10 hours warming to 98°C, 18 hours at 98°C, and then 12 hours at 177°C. Tensile strengths of these oven-cured samples were also obtained. Compression tests were also performed on the dogbone specimens after the tensile tests. The dogbone pieces were machined to approximately 3.66 cm (1.44 inches) in length providing a surface area of approximately 12.58 cm² (1.95 square inches), and a thickness of 2.22 cm (7/8 inch). The pressure to failure was recorded after heating for three hours up to 1000°C and maintaining 1000°C firing under nitrogen for one hour. The room temperature tensile strengths after 24 hours at room temperature and after oven curing, and the compressive failure test results are shown in Table I.

In a similar manner, a resole resin binder can be prepared within, for example, 15% of the phenol is replaced by a molar equivalent of m-cresol to form a phenol-cresol-formaldehyde resole resin.

Example 2 Preparation of Novolac Resin.

The novolac resin utilized in the trials reported in Tables II and IV was prepared as follows.

A reactor was charged with 981 grams (10.44 moles) phenol at 40°C and 2.0 grams of 93% sulfuric acid and heated to 77°C. Then 467 grams (7.783 moles) of formaldehyde was added over 60 minutes. The reaction was refluxed for 30 minutes and then distilled at atmospheric pressure to a temperature of 110°C. The residue was neutralized with a small amount of lime water slurry and the mixture distilled at atmospheric pressure to 149°C. Vacuum distillation was commenced down to 81.26 kPa (24 inches Hg.) at 149°C over a 20 minute period. The resulting resin product contained 6% free phenol, exhibited a drop melt point of 248°F (120°C) and an initial formaldehyde:phenol mole ratio of 0.746:1.

In a similar manner, phenol-cresol-formaldehyde novolac resins can be prepared by replacing up to about 20 mole per cent of the phenol by a molar equivalent of m-cresol.

In Tables I, II and IV, all mixtures contained 3% phenolic resin solids used as an aqueous, 50% solution. The ester in all cases was triacetin at 17% based on the weight of alkaline phenolic solution. Tensile strength measurements are an average of three samples. Densities of the specimens after 24 hours at room temperature for magnesia and alumina aggregate systems were 2.82 ± 0.02 gms/cc and after post oven-cure were 2.77 ± 0.02 gms/cc. Corresponding densities for sand aggregate mixtures were 1.78 ± 0.01 gms/cc room temperature and 1.77 ± 0.01 gms/cc for post oven-cure. For the sand aggregate systems of Table III, 2.5% by weight phenolic resin solids was used as a 60% solids aqueous solution.

Trial 1 on Table I was a comparative example using a resole resin-aggregate mixture prepared as in Example 1, above, but containing potassium at a potassium:phenol mole ratio of 0.63:1, rather than lithium. Trial 3 was also a comparative example and had a sodium:phenol mole ratio of 0.63:1 rather than lithium. For trial 2, the lithium ion-catalyzed resole resin alkali:phenol ratio included 0.05 potassium and exhibited significantly higher over-cured tensile strength and compressive strengths than did the sodium or potassium catalyzed resins. Reducing the alkali:phenol mole ratio to 0.34:1 (0.29:1 as lithium trial 4) produced post oven-cure tensile strength exceeding those obtained with significantly more potassium (trial 1) or sodium (trial 3) and no lithium. Trial 5 shows lithium ion catalyzed resole resins prepared as above, but with alkali:phenol mole ratios of 0.19:1 (0.14:1 as lithium). Trial 6 shows that the addition of hexa to a lithium catalyzed resole resin has only a slight effect. These two trials (5 and 6) had low but acceptable 24 hour room temperature cure green strengths (1971.9 and 1613.4 kPa (286 and 234 p.s.i.)) and significant oven-cured tensile and compressive values. Phenol-cresol-formaldehyde novolac resins will produce equivalent results.

Table II shows a comparison of lithium ion-catalyzed and potassium ion-catalyzed resole resin using alumina as the aggregate material. The alumina was a mixture of three parts of -14 to +28 mesh and one part of -28 to +14 mesh. While the room temperature strengths of trials 7 and 8 are comparable, the lithium ion-catalyzed resole-alumina mixture of trial 8 had a significantly superior tensile strength after oven curing (7274.2 kPa (1055 p.s.i.)) for lithium ion-catalyzed resole-alumina mixture as compared to 2075.4 kPa (301 p.s.i.) for potassium ion-catalyzed resole-alumina mixture. Table II also shows, in comparative trial 9, that use of a novolac resin cured with 10% hexa (based on resin solids) gave unacceptable room temperature strength and only 2302.9 kPa (334 p.s.i.) after oven cure.

Table III compares potassium ion- and lithium ion-catalyzed resole-sand mixtures. The sand utilized in the mixtures in Table III was AFS 50 size. While the tensile values are all low due to the absence of silane adhesion promoter usually used in sand mixtures, the post oven-cure tensile strength of the lithium ion-

catalyzed resole-sand specimen (trial 11) was significantly higher than the oven-cured tensile strength of the potassium ion-catalyzed resole-sand specimen (trial 10).

Table IV shows tensile strengths after 24 hour room temperature cure and post oven cure strengths for lithium ion-catalyzed resole (trial 13) and resole/novolac (1:1) binders (trial 15), with a magnesia/graphite blend of aggregate material, as compared to potassium ion-catalyzed resole resin (trial 12) and potassium ion-catalyzed 1:1 mix of resole and novolac. A phenol-cresol formaldehyde novolac resin, catalyzed with lithium ion according to the present invention, is expected to provide results comparable to the results in trial 15.

Table I

Alkali Ion-Catalyzed Resole-Magnesia Mixture

Trial No	Alkali	Alkali/phenol	Tensile, 10 ² kPa (psi) 24 hrs. r.t.	P.O.C.	Compressive kg (Lbs)
1	K ⁺	0.63:1	53.02 (769)	61.23 (888)	362.4 (800)
2	Li ⁺	0.63:1	30.89 (448)	115.97 (1682)	1374.9 (3035)
3	Na ⁺	0.63:1	51.99 (754)	68.40 (992)	1060 (2340)
4(a)	Li ⁺	0.34:1	27.17 (394)	83.57 (1212)	774.6 (1710)
5	Li ⁺	0.19:1	19.72 (286)	88.81 (1288)	887.9 (1960)
6	Li ⁺ + hexa(b)	0.19:1	16.13 (234)	79.43 (1152)	-----

7	K ⁺	0.63:1	44.68 (648)	52.40 (760)	912.8 (2015)
5	8	Li ⁺	0.63:1	31.37 (455)	103.84 (1506)
					1214 (2680)

The resole resin and binder/aggregate used were prepared as in Example 1.

P.O.C., "post oven-cure" herein, includes a heat history of 98°C for 18 hours and 12 hours at 177°C, cooling the test specimen to ambient conditions for measurement.

Compressive values (median of 3) were measured at room temperature as kg (pounds) of compression until failure of the specimen after 1000°C firing in a muffle furnace under nitrogen (prepurified, oxygen content less than 20 ppm) for one hour, after 3 to 3½ hour warming

cycle. Trials 1 and 2 above were not done with pre-purified nitrogen (oxygen content was up to 200 ppm).

The alkali/phenol molar ratios above include 0.05 as K⁺ which is residual ion from the resin preparation.

(a) Equivalent results were obtained from resin mixture containing 0.4% N-(2-aminoethyl)-gamma aminopropyl trimethoxysilane, 26020 from Dow Corning Corporation or 0.4% gamma-aminopropyl triethoxysilane, A1102 from Union Carbide Corporation.

(b) The hexa was present at a level of 5% by weight based on the weight of resole resin solids.

Table II

Resole-Alumina Aggregate Mixture						
Trial No	Resin	Alkali	Alkali/Phenol	Tensile 10 ² kPa (p.s.i.)		Compressive* kg (Lbs)
				24 hrs r.t.	P.O.C.	
7	Resole	K ⁺	0.63:1	41.92 (608)	20.75 (301)	17.21 (38)
8	Resole	Li ⁺	0.63:1	31.51 (457)	72.74 (1055)	132.73 (293)
9	novolac + hexa	--	-----	0 (0)	23.03 (334)	60.25 (133)

* Firing conducted with industrial grade nitrogen and not prepurified grade.

The resole resin was prepared as in Example 1.
The novolac was prepared as in Example 2.
The hexa was present in trial 9 at a level of 5% by weight based on the weight of novolac solids.

Table III

Resole-Sand Mixture					
Trial No	Resin	Alkali	Alkali/Phenol	Tensile 10 ² kPa (psi)	
				24 hrs. r.t.	P.O.C.
10	Resole	K ⁺	0.63:1	3.38 (49)	4.76 (69)
11	Resole	Li ⁺	0.63:1	2.69 (39)	13.03 (189)

The resole resin was prepared as in Example 1, above.

The resin binder was used at 2.5% phenolic solids based on weight of the sand.

Table IV

Magnesia/Graphite (90/10) Aggregate				
Trial No	Resin Mix	Alkali/Phenol	Room Temp Tensile Str 10 ² kPa (psi)	
			24 Hrs.	After P.O.C.
12	Resole (K ⁺)	0.63:1	41.50 (602)	59.50 (863)
13	Resole (Li ⁺)	0.63:1	31.30 (454)	67.92 (985)
14	Resole/novolac 1:1 (K ⁺)	0.57:1	47.16 (684)	103.49 (1501)
15	Resole/novolac 1:1 (Li ⁺)	0.57:1	41.16 (597)	111.70 (1620)

All with 17% triacetin on liquid resin weight.

The resole was prepared as in Example 1, above.

The novolac resin was prepared as in Example 2, above.

The resin binder was used at 3% by weight in the binder/aggregate mixture.

The resole/novolac ratios in trials 14 and 15 are by weight.

Claims

1. A curable binder composition comprising
 - (a) a phenol formaldehyde resole resin;
 - (b) an ester-functional curing agent in an amount sufficient to effect the ambient temperature cure of the resole resin; and,
 - (c) a lithium ion generating alkalinizing agent present in an amount sufficient to produce in the composition a mole ratio of lithium:phenol of from 0.1:1 to 1:1.
2. A binder composition according to claim 1, wherein the resole resin is the reaction product of a phenolic material and formaldehyde and wherein the formaldehyde:phenol molar ratio is between 1:1 and 3:1.
3. A binder composition according to claim 1, wherein the binder composition further comprises a phenol formaldehyde novolac component having a formaldehyde:phenol mole ratio in the range of 0.5:1 to 0.9:1, wherein said novolac and said resole are present in the binder composition in a weight ratio of novolac to resole of from 5:1 to 0.35:1.
4. A binder composition according to any one of claims 1 to 3, further comprising water.
5. A binder composition according to any one of claims 1 to 3, further comprising an organic solvent for the resin selected from C₁-C₇ aliphatic and aromatic alcohols, C₂-C₄ glycols, glycol ethers and mixtures thereof.
6. A binder composition according to any one of claims 1 to 5, wherein the lithium ion-generating alkalinizing agent is selected from lithium oxide, lithium hydroxide, lithium methoxide, lithium ethoxide, monolithium salt of ethylene glycol and mixtures thereof.
7. A binder-aggregate material comprising the curable binder composition according to claim 1 and a particulate aggregate material, wherein the weight ratio of resole resin to aggregate material is from 2:100 to 1:7.
8. A binder-aggregate material according to claim 7 further comprising a phenol formaldehyde novolac resin.
9. A binder-aggregate material according to claim 7 or claim 8 wherein the particulate aggregate material is selected from magnesia, alumina, zirconia, zircon sand, olivine sand, silicon carbide, silicon nitride,

boron nitride, silica, bauxite, corundum, pumice, perlite, vermiculite, limestone, quartz, sand, gravel, crushed rock, broken brick, air cooled blast furnace slag and mixtures thereof.

- 5 10. A binder composition according to claim 1, wherein the ester-functional curing agent is selected from lactones, cyclic organic carbonates, carboxylic acid esters, aromatic formates, aromatic acetates and mixtures thereof, and is present in an amount up to 40% by weight based on the weight of resole resin in the binder composition.
- 10 11. A binder-aggregate material according to any one of claims 7 to 9, wherein the ester-functional curing agent is selected from lactones, cyclic organic carbonates, carboxylic acid esters and mixtures thereof, and is present in an amount from 5% to 25% by weight based on the weight of the resole resin in the binder composition.
- 15 12. A binder-aggregate material according to claim 9, wherein the ester-functional curing agent is selected from diacetin, triacetin, butyro-lactone, caprolactone, methyl formate, ethyl formate, ethylene carbonate, propylene carbonate, dimethyl esters of succinic acid, glutaric acid and adipic acid, and mixtures thereof.
- 20 13. A binder aggregate material according to any one of claims 7 to 9, further comprising at least one additive additive selected from non-reactive solvents, silanes, clays, graphite, iron oxide, carbon pitch, silicon dioxide, aluminium powder, magnesium powder, silicon powder, calcium oxide, calcium hydroxide, magnesium oxide, magnesium hydroxide and mixtures thereof.
- 25 14. A binder composition according to claim 1 wherein the lithium ion-generating alkalizing agent is lithium hydroxide.
15. A binder composition according to claim 3 further comprising a methylene generating material selected from the group consisting of formaldehyde, hexamethylene tetramine and paraformaldehyde.
- 30 16. A curable binder composition according to claim 1 or claim 3 wherein the phenol formaldehyde resole resin is obtained from phenol, cresol and formaldehyde.
17. A curable binder composition according to claim 1 or claim 3 wherein the phenol formaldehyde resole resin is obtained from phenol, xylenol and formaldehyde.
- 35 18. A shaped article for use in making a refractory article comprising aggregate material bonded together by a cured binder composition, said binder composition in its uncured state containing a phenol formaldehyde resole resin, an ester-functional curing agent and a lithium ion-generating alkalizing agent selected from lithium oxide, lithium hydroxide, lithium methoxide, lithium ethoxide, monolithium salt of ethylene glycol and mixtures thereof, wherein the lithium ion-generating alkalizing agent is present in an amount sufficient to produce in the binder composition a mole ratio of lithium:phenol of from 0.1:1 to 1:1, and the ester-functional curing agent is present in an amount sufficient to cure at ambient temperature the resole resin and wherein the aggregate material is selected from magnesia, alumina, silica, zirconia, zircon sand, olivine sand, silicon carbide, silicon nitride, boron nitride, bauxite, corundum, pumice, perlite, vermiculite, limestone, quartz, sand, gravel, crushed rock, broken brick, air cooled blast furnace slag, and mixtures thereof.
- 45 19. A shaped article according to claim 18 further comprising at least one additive selected from the group consisting of non-reactive solvents, silanes, clays, graphite, iron oxide, carbon pitch, silicon dioxide, aluminium powder, magnesium powder, silicon powder, calcium oxide, calcium hydroxide, magnesium oxide, magnesium hydroxide and mixtures thereof.
- 50 20. A shaped article according to claim 19 wherein the binder composition further comprises a phenol formaldehyde novolac resin, wherein the weight ratio of novolac resin to resole resin is from 5:1 to 0.35:1.
- 55 21. A shaped article according to claim 19 or claim 20 comprising a phenol formaldehyde resole resin, an ester-functional curing agent, lithium oxide alkalizing agent and alumina.

22. A shaped article according to claim 19 or claim 20 comprising a phenol formaldehyde resole resin, an ester-functional curing agent, lithium oxide alkalizing agent and magnesia.

23. A shaped article comprising

- 5 (a) a phenol formaldehyde resin binder composition comprising in its uncured state
 (i) a phenol formaldehyde novolac resin having a formaldehyde:phenol mole ratio in the range of 0.5:1 to 0.9:1, and
 (ii) a phenol formaldehyde resole resin having a formaldehyde:phenol mole ratio in the range of 1:1 to 3:1,
 10 wherein said novolac and said resole resins are present in a weight ratio of novolac to resole of between 5:1 and 0.35:1 and wherein the phenol is selected from phenol, cresole and xylene;
 (b) an ester-functional curing agent;
 (c) lithium oxide alkalizing agent; and
 (d) an aggregate material selected from silica, alumina and magnesia present in an amount up to
 15 97% by weight of the shaped article,
 and wherein the pH of the resin binder composition is sufficiently alkaline to cure the resin binder composition at ambient temperature and bind the aggregate material into a desired shape.

20 24. A shaped article according to claim 23 further comprising at least one additive selected from graphite, aluminium powder, magnesium powder, silicon powder, calcium oxide, calcium hydroxide, magnesium oxide, and magnesium hydroxide, wherein the aggregate is present in the shaped article in an amount from 70 to 97% by weight.

25 25. A shaped article according to claim 23 further comprising a silane adhesion promoter, wherein the aggregate is alumina or silica.

26. A process for making a refractory body that can be heated to form a carbonized article, said process comprising the steps of

- 30 (a) Mixing a resin binder composition comprising
 (i) a resole resin having a formaldehyde:phenol molar ratio in the range of about 1:1 to about 3:1,
 (ii) an ester-functional curing agent in an amount sufficient to affect the ambient temperature cure of the resole resin, and
 (iii) a lithium ion-generating alkalizing agent selected from lithium oxide, lithium hydroxide, lithium methoxide, lithium ethoxide, monolithium salt of ethylene glycol and mixtures thereof, wherein the
 35 lithium ion-generating alkalizing agent is present at a level sufficient to provide an alkali:phenol molar ratio in the resin binder composition of 0.1:1 to 1:1,
 with an aggregate material selected from magnesia, alumina, silica, zirconia, zircon sand, olivine sand, silicon carbide, silicon nitride, boron nitride, bauxite, corundum, pumice, perlite, vermiculite, limestone, quartz, sand, gravel, crushed rock, broken brick, air cooled blast furnace slag and mixtures thereof, wherein the weight ratio of resole resin to aggregate material is in the range of
 40 from 3:100 to 1:7, whereby a binder-aggregate mixture is prepared;
 (b) forming said binder-aggregate mixture of step (a) into a shaped article; and
 (c) heating the shaped article to make a refractory body.

45 27. A process according to claim 26 further comprising curing at ambient temperature the shaped article of step (b) prior to the heating of step (c).

28. A process according to claim 26 wherein the resin binder composition of step (a) further comprises a phenol formaldehyde novolac resin, wherein the formaldehyde to phenol mole ratio of the novolac resin
 50 is from 0.5:1 to 0.9:1.

29. A process according to claim 26 wherein the ester-functional curing agent is selected from lactones, cyclic organic carbonates, carboxylic acid esters and mixtures thereof, and is present in the resin binder at a level of from 5% to 25% based on the weight of the resole resin.

55 30. A process for making a refractory body that can be heated to form a carbonized article, said process comprising the steps of
 (a) mixing a resin binder composition comprising

- (i) a resole resin having a formaldehyde:phenol molar ratio in the range of 1:1 to 3:1, and
- (ii) a lithium ion-generating alkalizing agent selected from lithium oxide, lithium hydroxide, lithium methoxide, lithium ethoxide, monolithium salt of ethylene glycol and mixtures thereof, wherein the lithium ion-generating alkalizing agent is present at a level sufficient to provide an alkali:phenol molar ratio in the resin binder composition of 0.1:1 to 1:1,

with an aggregate material selected from magnesia, alumina, silica, zirconia, zircon sand, olivine sand, silicon carbide, silicon nitride, boron nitride, bauxite, corundum, pumice, perlite, vermiculite, limestone, quartz, sand, gravel, crushed rock, broken brick, air cooled blast furnace slag and mixtures thereof, wherein the weight ratio of resole resin to aggregate material is in the range of 2:100 to 1:7, whereby a binder-aggregate mixture is prepared;

- (b) forming said binder-aggregate mixture of step (a) into a shaped article;
- (c) gassing the shaped article with at least one C₁-C₃ alkyl formate to cure the resin binder composition; and
- (d) heating the shaped article to make a refractory body.

31. A substrate coated with the composition of claim 1.

32. A coated substrate as claimed in claim 31 wherein the substrate is concrete.

Patentansprüche

1. Härtbare Bindermasse, umfassend

- (a) ein Phenol/Formaldehyd-Resolharz;
- (b) ein esterfunktionelles Härtungsmittel in einer ausreichenden Menge, um eine Härtung des Resolharzes bei Umgebungstemperatur zu bewirken, und
- (c) ein Lithiumionen-bildendes Alkalisierungsmittel, das in einer ausreichenden Menge vorhanden ist, um in der Masse ein Molverhältnis Lithium zu Phenol von 0,1:1 bis 1:1 zu bilden.

2. Bindermasse nach Anspruch 1, wobei das Resolharz das Reaktionsprodukt eines phenolischen Materials mit Formaldehyd ist und wobei das Molverhältnis Formaldehyd zu Phenol zwischen 1:1 und 3:1 liegt.

3. Bindermasse nach Anspruch 1, wobei die Bindermasse zusätzlich eine Phenol/Formaldehyd-Novolak-Komponente mit einem Molverhältnis Formaldehyd zu Phenol im Bereich von 0,5:1 bis 0,9:1 enthält, wobei der Novolak und das Resol in der Bindermasse in einem Gewichtsverhältnis Novolak zu Resol von 5:1 bis 0,35:1 vorhanden sind.

4. Bindermasse nach einem der Ansprüche 1 bis 3, die zusätzlich Wasser enthält.

5. Bindermasse nach einem der Ansprüche 1 bis 3, die zusätzlich ein organisches Lösungsmittel für das Harz, ausgewählt aus aliphatischen C₁-C₇- und aromatischen Alkoholen, C₂-C₄-Glykolen, Glykolethern und Gemischen davon enthält.

6. Bindermasse nach einem der Ansprüche 1 bis 5, wobei das Lithiumionen-entwickelnde Alkalisierungsmittel ausgewählt ist aus Lithiumoxid, Lithiumhydroxid, Lithiummethoxid, Lithiumethoxid, Monolithiumsalz von Ethylenglykol und Gemischen davon.

7. Binder/Aggregat-Material, umfassend die härtbare Bindermasse nach Anspruch 1 und ein teilchenförmiges Aggregat-(bzw. Zuschlag)material, wobei das Gewichtsverhältnis von Resolharz zu Aggregatmaterial 2:100 bis 1:7 beträgt.

8. Binder/Aggregat-Material nach Anspruch 7, das zusätzlich ein Phenol/Formaldehyd-Novolakharz enthält.

9. Binder/Aggregat-Material nach Anspruch 7 oder Anspruch 8, wobei das teilchenförmige Aggregatmaterial ausgewählt ist aus Magnesia, Tonerde, Zirkonia, Zirkonsand, Olivinsand, Siliciumcarbid, Siliciumnitrid, Bornitrid, Kieselsäure, Bauxit, Korund, Bimsstein, Perlit, Vermikulit, Kalkstein, Quarz, Sand, Kies, zerstoßenem Gestein, zerbrochenem Ziegel, an der Luft gekühlter Hochofenschlacke und Gemischen davon.

10. Bindermasse nach Anspruch 1, wobei das esterfunktionelle Härtungsmittel ausgewählt ist aus Lactonen, cyclischen organischen Carbonaten, Carbonsäureestern, aromatischen Formiaten, aromatischen Acetaten und Gemischen davon und in einer Menge von bis zu 40 Gew.-%, bezogen auf das Gewicht des Resolharzes, in der Bindermasse vorhanden ist.
- 5 11. Binder/Aggregat-Material nach einem der Ansprüche 7 bis 9, wobei das esterfunktionelle Härtungsmittel ausgewählt ist aus Lactonen, cyclischen organischen Carbonaten, Carbonsäureestern und Gemischen davon und in einer Menge von 5 bis 25 Gew.-%, bezogen auf das Gewicht des Resolharzes, in der Bindermasse vorhanden ist.
- 10 12. Binder/Aggregat-Material nach Anspruch 9, wobei das esterfunktionelle Härtungsmittel ausgewählt ist aus Diacetin, Triacetin, Butyrolacton, Caprolacton, Methylformiat, Ethylformiat, Ethylencarbonat, Propylencarbonat, Dimethylestern von Bernsteinsäure, Glutarsäure und Adipinsäure und Gemischen davon.
- 15 13. Binderaggregatmaterial nach einem der Ansprüche 7 bis 9, das zusätzlich mindestens ein Additiv enthält, ausgewählt aus nicht reaktionsfähigen Lösungsmitteln, Silanen, Tonen, Graphit, Eisenoxid, Kohlepech, Siliciumdioxid, Aluminiumpulver, Magnesiumpulver, Siliciumpulver, Calciumoxid, Calciumhydroxid, Magnesiumoxid, Magnesiumhydroxid und Gemischen davon.
- 20 14. Bindermasse nach Anspruch 1, wobei das Lithiumionen-entwickelnde Alkalisierungsmittel Lithiumhydroxid ist.
15. Bindermasse nach Anspruch 3, die zusätzlich ein Methylen erzeugendes Material enthält, ausgewählt aus der Gruppe bestehend aus Formaldehyd, Hexamethylentetramin und Paraformaldehyd.
- 25 16. Härtbare Bindermasse nach Anspruch 1 oder Anspruch 3, wobei das Phenol/Formaldehyd-Resolharz erhalten worden ist aus Phenol, Kresol und Formaldehyd.
17. Härtbare Bindermasse nach Anspruch 1 oder Anspruch 3, wobei das Phenol/Formaldehyd-Resolharz erhalten worden ist aus Phenol, Xylenol und Formaldehyd.
- 30 18. Formkörper zur Verwendung bei der Herstellung eines feuerfesten Gegenstandes, umfassend Aggregatmaterial, das gebunden ist durch eine gehärtete Bindermasse, wobei die Bindermasse in ungehärtetem Zustand ein Phenol/Formaldehyd-Resolharz, ein esterfunktionelles Härtungsmittel und ein Lithiumionen-entwickelndes Alkalisierungsmittel, ausgewählt aus Lithiumoxid, Lithiumhydroxid, Lithiummethoxid, Lithiummethoxid, Monolithiumsalz von Ethylenglykol und Gemischen davon, umfaßt, wobei das Lithiumionen-entwickelnde Alkalisierungsmittel in einer ausreichenden Menge vorhanden ist, um in der Bindermasse ein Molverhältnis von Lithium zu Phenol von 0,1:1 bis 1:1 zu erzeugen, und das esterfunktionelle Härtungsmittel in einer ausreichenden Menge vorhanden ist, um das Resolharz bei Umgebungstemperatur zu härten, und wobei das Aggregatmaterial ausgewählt ist aus Magnesia, Tonerde, Kieselsäure, Zirkonia, Zirkonsand, Olivinsand, Siliciumcarbid, Siliciumnitrid, Bornitrid, Bauxit, Korund, Bimsstein, Perlit, Vermikulit, Kalkstein, Quarz, Sand, Kies, zerstoßenem Gestein, zerbrochenem Ziegel, luftgekühlter Hochofenschlacke und Gemischen davon.
- 35 19. Formkörper nach Anspruch 18, der zusätzlich ein Additiv enthält, ausgewählt aus der Gruppe bestehend aus nicht-reaktionsfähigen Lösungsmitteln, Silanen, Tonen, Graphit, Eisenoxid, Kohlepech, Siliciumdioxid, Aluminiumpulver, Magnesiumpulver, Siliciumpulver, Calciumoxid, Calciumhydroxid, Magnesiumoxid, Magnesiumhydroxid und Gemischen davon.
- 40 20. Formkörper nach Anspruch 19, wobei die Bindermasse zusätzlich ein Phenol/Formaldehyd-Novolakharz enthält, wobei das Gewichtsverhältnis von Novolakharz zu Resolharz 5:1 bis 0,35:1 beträgt.
21. Formkörper nach Anspruch 19 oder Anspruch 20, umfassend ein Phenol/Formaldehyd-Resolharz, ein esterfunktionelles Härtungsmittel, Lithiumoxid als Alkalisierungsmittel und Tonerde.
- 55 22. Formkörper nach Anspruch 19 oder Anspruch 20, umfassend ein Phenol/Formaldehyd-Resolharz, ein esterfunktionelles Härtungsmittel, Lithiumoxid als Alkalisierungsmittel und Magnesia.

23. Formkörper, umfassend
- (a) eine Phenol/Formaldehydharz-Bindermasse, umfassend in ungehärtetem Zustand
 - (i) ein Phenol/Formaldehyd-Novolakharz mit einem Molverhältnis Formaldehyd zu Phenol im Bereich von 0,5:1 bis 0,9:1, und
 - (ii) ein Phenol/Formaldehyd-Resolharz mit einem Molverhältnis Formaldehyd zu Phenol im Bereich von 1:1 bis 3:1,
 wobei das Novolak- und Resolharz in einem Gewichtsverhältnis von Novolak zu Resol zwischen 5:1 und 0,35:1 vorhanden sind, und wobei das Phenol ausgewählt ist aus Phenol, Kresol und Xylenol;
 - (b) ein esterfunktionelles Härtungsmittel;
 - (c) Lithiumoxid als Alkalisierungsmittel und
 - (d) ein Aggregatmaterial, ausgewählt aus Kieselsäure, Tonerde und Magnesia in einer Menge von bis zu 97 Gew.-%, bezogen auf den Formkörper;
- und wobei der pH-Wert der Harz-Bindermasse ausreichend alkalisch ist, um die Harz-Bindermasse bei Umgebungstemperatur zu härten und das Aggregatmaterial in der gewünschten Form zu binden.
24. Formkörper nach Anspruch 23, der zusätzlich mindestens ein Additiv enthält, ausgewählt aus Graphit, Aluminiumpulver, Magnesiumpulver, Siliciumpulver, Calciumoxid, Calciumhydroxid, Magnesiumoxid und Magnesiumhydroxid, wobei das Aggregatmaterial in dem Formkörper in einer Menge von 70 bis 97 Gew.-% vorhanden ist.
25. Formkörper nach Anspruch 23, der zusätzlich einen Silanhaftungsbeschleuniger enthält, wobei das Aggregatmaterial Tonerde oder Kieselsäure ist.
26. Verfahren zur Herstellung eines feuerfesten Körpers, der erhitzt werden kann, um einen carbonisierten Körper zu erhalten, wobei das Verfahren die folgenden Stufen umfaßt:
- (a) Vermischen einer Harz-Bindermasse, umfassend
 - (i) ein Resolharz mit einem Molverhältnis Formaldehyd zu Phenol im Bereich von etwa 1:1 bis etwa 3:1,
 - (ii) ein esterfunktionelles Härtungsmittel in einer ausreichenden Menge, um das Resolharz bei Umgebungstemperatur zu härten, und
 - (iii) ein Lithiumionen-entwickelndes Alkalisierungsmittel, ausgewählt aus Lithiumoxid, Lithiumhydroxid, Lithiummethoxid, Lithiumethoxid, Monolithiumsalz von Ethylenglykol und Gemischen davon, wobei das Lithiumionen-entwickelnde Alkalisierungsmittel in einer ausreichenden Menge vorhanden ist, um ein Molverhältnis Alkali zu Phenol in der Harz-Bindermasse von 0,1:1 bis 1:1 zu ergeben,
 mit einem Aggregatmaterial, ausgewählt aus Magnesia, Tonerde, Kieselsäure, Zirkonia, Zirkonsand, Olivinsand, Siliciumcarbid, Siliciumnitrid, Bornitrid, Bauxit, Korund, Bimsstein, Perlit, Vermikulit, Kalkstein, Quarz, Sand, Kies, zerstoßenem Gestein, zerbrochenem Ziegel, luftgekühlter Hochofenschlacke und Gemischen davon, wobei das Gewichtsverhältnis von Resolharz zu Aggregatmaterial im Bereich von 3:100 bis 1:7 liegt, wodurch ein Binder/Aggregat-Gemisch hergestellt wird;
 - (b) Formen des Binder/Aggregat-Gemisches der Stufe (a) zu einem Formkörper und
 - (c) Erhitzen des Formkörpers zur Erzeugung eines feuerfesten Körpers.
27. Verfahren nach Anspruch 26, umfassend ferner das Härten des geformten Körpers der Stufe (b) bei Umgebungstemperatur vor dem Erhitzen der Stufe (c).
28. Verfahren nach Anspruch 26, wobei die Harz-Bindermasse der Stufe (a) zusätzlich ein Phenol/Formaldehyd-Novolakharz enthält, wobei das Molverhältnis Formaldehyd zu Phenol in dem Novolakharz 0,5:1 bis 0,9:1 beträgt.
29. Verfahren nach Anspruch 26, wobei das esterfunktionelle Härtungsmittel ausgewählt ist aus Lactonen, cyclischen organischen Carbonaten, Carbonsäureestern und Gemischen davon und in dem Harzbinder in einer Menge von 5 bis 25%, bezogen auf das Gewicht des Resolharzes, vorhanden ist.
30. Verfahren zur Herstellung eines feuerfesten Körpers, der zur Erzeugung eines carbonisierten Körpers erhitzt werden kann, wobei das Verfahren die folgenden Stufen umfaßt:
- (a) Vermischen einer Harz-Bindermasse, umfassend

- (i) ein Resolharz mit einem Molverhältnis Formaldehyd zu Phenol im Bereich von etwa 1:1 bis etwa 3:1,
 (ii) ein Lithiumionen-entwickelndes Alkalisierungsmittel, ausgewählt aus Lithiumoxid, Lithiumhydroxid, Lithiummethoxid, Lithiumethoxid, Monolithiumsalz von Ethylenglykol und Gemischen davon, wobei das Lithiumionen-entwickelnde Alkalisierungsmittel in einer ausreichenden Menge vorhanden ist, um ein Molverhältnis Alkali zu Phenol in der Harz-Bindermasse von 0,1:1 bis 1:1 zu ergeben,
 mit einem Aggregatmaterial, ausgewählt aus Magnesia, Tonerde, Kieselsäure, Zirkonia, Zirkonsand, Olivinsand, Siliciumcarbid, Siliciumnitrid, Bornitrid, Bauxit, Korund, Bimsstein, Perlit, Vermikulit, Kalkstein, Quarz, Sand, Kies, zerstoßenem Gestein, zerbrochenem Ziegel, luftgekühlter Hochofenschlacke und Gemischen davon, wobei das Gewichtsverhältnis von Resolharz zu Aggregatmaterial im Bereich von 2:100 bis 1:7 liegt, zur Bildung eines Binder/Aggregat-Gemisches;
 (b) Formen des Binder/Aggregat-Gemisches der Stufe (a) zu einem Formkörper und
 (c) Begasen des Formkörpers mit mindestens einem C₁-C₃-Alkylformiat, um die Harz-Bindermasse zu härten, und
 (d) Erhitzen des Formkörpers zur Erzeugung eines feuerfesten Körpers.

31. Substrat, überzogen mit der Masse nach Anspruch 1.

32. Überzogenes Substrat nach Anspruch 31, wobei das Substrat Beton ist.

Revendications

1. Une composition de liant polymérisable comprenant
 - (a) une résine résol à base de phénol-formaldéhyde
 - (b) un agent de polymérisation fonctionnel ester en quantité suffisante pour réaliser la polymérisation à température ambiante de la résine résol ; et
 - (c) un agent d'alcalinisation générateur d'ions de lithium présent en quantité suffisante pour produire dans la composition un rapport molaire lithium/phénol de 0,1:1 à 1:1.
2. Une composition de liant selon la revendication 1, dans laquelle la résine résol est le produit de réaction d'une matière phénolique et de formaldéhyde et dans laquelle le rapport molaire formaldéhyde/phénol est compris entre 1:1 et 3:1.
3. Une composition de liant selon la revendication 1, dans laquelle la composition de liant comprend en outre un composant novolac à base de phénol/formaldéhyde ayant un rapport molaire formaldéhyde/phénol de l'ordre de 0,5:1 à 0,9:1, dans laquelle le novolac et le résol sont présents dans la composition de liant à un rapport de poids novolac/résol de 5:1 à 0,35:1.
4. Une composition de liant selon l'une ou l'autre des revendications 1 à 3, comprenant en outre de l'eau.
5. Une composition de liant selon l'une ou l'autre des revendications 1 à 3, comprenant en outre un solvant organique pour la résine sélectionné parmi les alcools aliphatiques et aromatiques C₁-C₇, les glycols C₂-C₄, les éthers de glycol et des mélanges de ceux-ci.
6. Une composition de liant selon l'une ou l'autre des revendications 1 à 5, dans laquelle l'agent d'alcalinisation générateur d'ions de lithium est sélectionné parmi l'oxyde de lithium, l'hydroxyde de lithium, le méthoxyde de lithium, l'éthoxyde de lithium, le sel de monolithium de l'éthylène-glycol et des mélanges de ceux-ci.
7. Un mélange liant-agrégats comprenant la composition de liant polymérisable selon la revendication 1 et un matériau d'agréments particulaire, dans lequel le rapport de poids résine résol/agrégats est de 2:100 à 1:7.
8. Un mélange liant-agrégats selon la revendication 7 comprenant en outre une résine novolac à base de phénol-formaldéhyde.

9. Un mélange liant-agrégats selon la revendication 7 ou la revendication 8 dans lequel le matériau d'agréats particulaire est sélectionné parmi la magnésie, l'alumine, le zircon, le sable de zircon, le sable d'olivine, le carbure de silicium, le nitrure de silicium, la silice, la bauxite, le corindon, la pierre ponce, la perlite, la vermiculite, le calcaire, le quartz, le sable, le gravier, la pierre concassée, la brique cassée, le laitier de haut fourneau refroidi à l'air et des mélanges de ceux-ci.
5
10. Une composition de liant selon la revendication 1, dans laquelle l'agent de polymérisation fonctionnel ester est sélectionné parmi les lactones, les carbonates organiques cycliques, les esters d'acides carboxyliques, les formates aromatiques, les acétates aromatiques et des mélanges de ceux-ci, et est présent en une quantité maximum de 40 % en poids de la résine résol dans la composition de liant.
10
11. Un mélange liant-agrégats selon l'une ou l'autre des revendications 7 à 9, dans lequel l'agent de polymérisation fonctionnel ester est sélectionné parmi les lactones, les carbonates organiques cycliques, les esters d'acides carboxyliques et des mélanges de ceux-ci, et est présent à raison de 5 % à 25 % en poids de la résine résol dans la composition de liant.
15
12. Un mélange liant-agrégats selon la revendication 9, dans lequel l'agent de polymérisation fonctionnel ester est sélectionné parmi la diacétine, la triacétine, la butyrolactone, la caprolactone, le formate de méthyle, le formate d'éthyle, le carbonate d'éthylène, le carbonate de propylène, les esters diméthyliques de l'acide succinique, de l'acide glutarique et de l'acide adipique, et des mélanges de ceux-ci.
20
13. Un mélange liant-agrégats selon l'une ou l'autre des revendications 7 à 9, comprenant en outre au moins un additif sélectionné parmi les solvants non réactifs, les silanes, les argiles, le graphite, l'oxyde de fer, le brai de houille, le dioxyde de silicium, la poudre d'aluminium, la poudre de magnésium, la poudre de silicium, l'oxyde de calcium, l'hydroxyde de calcium, l'oxyde de magnésium, l'hydroxyde de magnésium et des mélanges de ceux-ci.
25
14. Une composition de liant selon la revendication 1 dans laquelle l'agent d'alcalinisation générateur d'ions de lithium est l'hydroxyde de lithium.
30
15. Une composition de liant selon la revendication 3 comprenant en outre une matière génératrice de méthylène sélectionnée dans le groupe constitué du formaldéhyde, de la tétramine d'hexaméthylène et du paraformaldéhyde.
35
16. Une composition de liant polymérisable selon la revendication 1 ou la revendication 3 dans laquelle la résine résol à base de phénol-formaldéhyde est obtenue à partir de phénol, de crésol et de formaldéhyde.
40
17. Une composition de liant polymérisable selon la revendication 1 ou la revendication 3 dans laquelle la résine résol à base de phénol-formaldéhyde est obtenue à partir de phénol, de xylénol et de formaldéhyde.
45
18. Un article façonné destiné à la fabrication d'un article réfractaire comprenant des agrégats liés ensemble par une composition de liant polymérisé, cette composition de liant contenant, à l'état non polymérisé, une résine résol à base de phénol-formaldéhyde, un agent de polymérisation fonctionnel ester et un agent d'alcalinisation générateur d'ions de lithium sélectionné parmi l'oxyde de lithium, l'hydroxyde de lithium, le méthoxyde de lithium, l'éthoxyde de lithium, le sel de monolithium de l'éthylène-glycol et des mélanges de ceux-ci, dans laquelle l'agent d'alcalinisation générateur d'ions de lithium est présent en quantité suffisante pour produire dans la composition de liant un rapport molaire lithium/phénol de 0,1:1 à 1:1, et l'agent de polymérisation fonctionnel ester est présent en quantité suffisante pour polymériser la résine résol à température ambiante, le matériau des agrégats étant sélectionné parmi la magnésie, l'alumine, la silice, le zircon, le sable de zircon, le sable d'olivine, le carbure de silicium, le nitrure de silicium, le nitrure de bore, la bauxite, le corindon, la pierre ponce, la perlite, la vermiculite, le calcaire, le quartz, le sable, le gravier, la pierre concassée, la brique cassée, le laitier de haut fourneau refroidi à l'air, et des mélanges de ceux-ci.
50
55
19. Un article façonné selon la revendication 18 comprenant en outre au moins un additif sélectionné dans le groupe constitué de solvants non réactifs, de silanes, d'argiles, de graphite, d'oxyde de fer, de brai

de houille, de dioxyde de silicium, de poudre d'aluminium, de poudre de magnésium, de poudre de silicium, d'oxyde de calcium, d'hydroxyde de calcium, d'oxyde de magnésium, d'hydroxyde de magnésium et de mélanges de ceux-ci.

- 5 20. Un article façonné selon la revendication 19 dans lequel la composition de liant comprend en outre une résine novolac à base de phénol-formaldéhyde et dans lequel le rapport de poids résine novolac/résine résol est de 5:1 à 0,35:1.
- 10 21. Un article façonné selon la revendication 19 ou la revendication 20 comprenant une résine résol à base de phénol-formaldéhyde, un agent de polymérisation fonctionnel ester, un agent d'alcalinisation à base d'oxyde de lithium et de l'alumine.
- 15 22. Un article façonné selon la revendication 19 ou la revendication 20 comprenant une résine résol à base de phénol-formaldéhyde, un agent de polymérisation fonctionnel ester, un agent d'alcalinisation à base d'oxyde de lithium et de la magnésie.
23. Un article façonné comprenant
 - (a) une composition de liant résine à base de phénol-formaldéhyde comprenant à l'état non polymérisé
 - 20 (i) une résine novolac à base de phénol-formaldéhyde ayant un rapport molaire formaldéhyde/phénol de l'ordre de 0,5:1 à 0,9:1, et
 - (ii) une résine résol à base de phénol-formaldéhyde ayant un rapport molaire formaldéhyde/phénol de l'ordre de 1:1 à 3:1,
 dans laquelle les résines novolac et résol sont présentes à un rapport de poids novolac/résol compris entre 5:1 et 0,35:1 et dans laquelle le phénol est sélectionné parmi le phénol, le crésol et le xylénol ;
 - 25 (b) un agent de polymérisation fonctionnel ester ;
 - (c) un agent d'alcalinisation à base d'oxyde de lithium ; et
 - (d) un matériau d'agréats sélectionné parmi la silice, l'alumine et la magnésie, présent jusqu'à 97
 - 30 % en poids de l'article façonné,
 et dans lequel le pH de la composition de liant résine est suffisamment alcaline pour polymériser la composition de liant résine à température ambiante et lier le matériau des agrégats pour donner une forme désirée.
 - 35 24. Un article façonné selon la revendication 23 comprenant en outre au moins un additif sélectionné parmi le graphite, la poudre d'aluminium, la poudre de magnésium, la poudre de silicium, l'oxyde de calcium, l'hydroxyde de calcium, l'oxyde de magnésium et l'hydroxyde de magnésium, les agrégats étant présents dans l'article façonné à raison de 70 à 97 % en poids.
 - 40 25. Un article façonné selon la revendication 23 comprenant en outre un activateur d'adhérence à base de silane, dans lequel le matériau des agrégats est de l'alumine ou de la silice.
 26. Un procédé pour fabriquer un élément réfractaire qui peut être chauffé pour former un article carbonisé, ce procédé comprenant les phases suivantes :
 - 45 (a) Mélange d'une composition de liant résine comprenant
 - (i) une résine résol ayant un rapport molaire formaldéhyde/phénol de l'ordre d'environ 1:1 à environ 3:1,
 - (ii) un agent de polymérisation fonctionnel ester en quantité suffisante pour permettre la polymérisation à température ambiante de la résine résol, et
 - 50 (iii) un agent d'alcalinisation générateur d'ions de lithium sélectionné parmi l'oxyde de lithium, l'hydroxyde de lithium, le méthoxyde de lithium, l'éthoxyde de lithium, le sel de monolithium de l'éthylène glycol et des mélanges de ceux-ci, l'agent d'alcalinisation générateur d'ions de lithium étant présent à un niveau suffisant pour assurer un rapport molaire alcali/phénol de 0,1:1 à 1:1 dans la composition de liant résine,
 - 55 avec un matériau d'agréats sélectionné parmi la magnésie, l'alumine, la silice, le zircon, le sable de zircon, le sable d'olivine, le carbure de silicium, le nitrure de silicium, le nitrure de bore, la bauxite, le corindon, la pierre ponce, la perlite, la vermiculite, le calcaire, le quartz, le sable, le gravier, la pierre concassée, la brique cassée, le laitier de haut fourneau refroidi à l'air et des

mélanges de ceux-ci, le rapport de poids résine résol/matériau d'agréats étant de l'ordre de 3:100 à 1:7, et permettant de préparer un mélange liant-agréats ;

- (b) façonnage du mélange liant-agréats de la phase (a) en un article façonné ; et
(c) chauffage de l'article façonné pour produire un élément réfractaire.

5

27. Un procédé selon la revendication 26 comprenant en outre la polymérisation à température ambiante de l'article façonné de la phase (b) avant le chauffage de la phase (c).

10

28. Un procédé selon la revendication 26 dans lequel la composition de liant résine de la phase (a) comprend en outre une résine novolac à base de phénol-formaldéhyde, le rapport molaire formaldéhyde/phénol de la résine étant de 0,5:1 à 0,9:1.

15

29. Un procédé selon la revendication 26 dans lequel l'agent de polymérisation fonctionnel ester est sélectionné parmi les lactones, les carbonates organiques cycliques, les esters d'acides carboxyliques et des mélanges de ceux-ci, et est présent dans le liant résine à un niveau de 5 % à 25 % en poids de la résine résol.

20

30. Un procédé pour fabriquer un élément réfractaire qui peut être chauffé pour former un article carbonisé, ce procédé comprenant les phases suivantes :

(a) mélange d'une composition de liant résine comprenant

25

- (i) une résine résol ayant un rapport molaire formaldéhyde/phénol de l'ordre de 1:1 à 3:1, et
(ii) un agent d'alcalinisation générateur d'ions de lithium sélectionné parmi l'oxyde de lithium, l'hydroxyde de lithium, le méthoxyde de lithium, l'éthoxyde de lithium, le sel de monolithium de l'éthylène glycol et des mélanges de ceux-ci, l'agent d'alcalinisation générateur d'ions de lithium étant présent à un niveau suffisant pour assurer un rapport molaire alcali/phénol de 0,1:1 à 1:1 dans la composition de liant résine,

30

avec un matériau d'agréats sélectionné parmi la magnésie, l'alumine, la silice, le zircon, le sable de zircon, le sable d'olivine, le carbure de silicium, le nitrure de silicium, le nitrure de bore, la bauxite, le corindon, la pierre ponce, la perlite, la vermiculite, le calcaire, le quartz, le sable, le gravier, la pierre concassée, la brique cassée, le laitier de haut fourneau refroidi à l'air et des mélanges de ceux-ci, le rapport de poids résine résol/matériau d'agréats étant de l'ordre de 2:100 à 1:7, permettant la préparation d'un mélange liant/agréats ;

35

- (b) façonnage du mélange liant/agréats de la phase (a) en un article façonné ;
(c) gazéification de l'article façonné avec au moins un formate d'alcoyle C₁-C₃ pour polymériser la composition de liant résine ; et
(d) chauffage de l'article façonné pour fabriquer l'élément réfractaire.

31. Un substrat enduit de la composition de la revendication 1.

40

32. Un substrat enduit selon la revendication 31 dans lequel le substrat est du béton.
